Model Aircraft Regulations
Governing Sporting Model Aviation in America
Issued by the Contest Boards of the
ACADEMY OF MODEL AERONAUTICS
Under the Franchise of
NATIONAL AERONAUTIC ASSOCIATION
and
FEDERATION AERONAUTIQUE INTERNATIONALE
22. RADIO CONTROL PATTERN EVENT REGULATIONS

22.1 OBJECTIVE: To control by radio a model airplane so that various planned maneuvers may be accomplished. The criterion is the quality of performance, not the mechanism of control. R/C competition shall be based on the excellence of performance of the model's maneuvers compared to similar maneuvers performed by a full size plane. Maneuvers shall be judged according to the AMA Radio Control Judges Guide.

22.2 MODEL AIRCRAFT REQUIREMENTS:

22.2.1 Models shall be of the reciprocating internal combustion engine powered type. Except as noted elsewhere, no model may weigh more than 15 lbs. gross weight, ready for takeoff. Total displacement of engine(s) shall not exceed .6102 cubic inches (10 cc).

22.2.2 There shall be no radio equipment or aircraft control function limitations in any pattern class. (Radio equipment is only limited by FCC regulations as specified below).

22.2.3 Two airplanes may be entered by a contestant and are to be numbered “1” and “2”. The contestant may choose to enter either plane at the beginning of the event and shall continue to use such plane throughout unless, and until, said plane is damaged to the extent that it cannot be readily repaired. Contestant then may, upon notifying the Contest Director, substitute the second plane for the balance of the meet without penalty. Once this has been done, the contestant may not re-submit the first plane later in the same contest.

22.2.4 The Builder of The Model rule will only apply to those R/C events in which points for appearance and workmanship are a factor. By this definition the rule does not apply to any of the pattern events.

22.2.5 All models entered in radio control competition shall be identified by the contestant’s AMA license number permanently affixed to the upper side of the right-hand lifting surface or to each side of the fuselage or vertical stabilizer. Unless otherwise stated, height of the numerals must be at least one inch. Both stroke and width shall be such as to enable ready recognition. It is suggested that the letters “N” be placed in front of the license number when the number is affixed to the side of the fuselage or vertical stabilizer.

22.3. SAFETY REQUIREMENTS: Considerations of safety for spectators, contestants, personnel, and other contestants are of the utmost importance in this event, and the following safety provisions must be observed.

22.3.1 All models must pass a general safety inspection by the Event Director or his representatives before they are allowed to compete.

22.3.2 If any part of a maneuver is performed over a controlled spectator area the contestant shall receive a zero score for that maneuver. Continued flying over controlled spectator areas by any one contestant shall result in disqualification of the contestant by the Event Director.

22.3.3 Dangerous flying of any sort, or poor sportsmanship of any kind, shall be grounds for disqualification of the contestant involved.

22.3.4 All planes entered must have rounded propeller tips, or some sort of safety cover on end of propeller shaft (such as a rounded “acorn nut”). Radius of point shall not be less than ¾ inch.

22.3.5 Knife edge wings are not allowed.

22.4 LICENSING REQUIREMENTS: All radio equipment and operation must conform to the regulations of the F.C.C., AMA membership card and F.C.C. license of each entrant shall be checked at every sanctioned meet.

22.5 GENERAL EVENT REGULATIONS: The Pattern Event shall be divided into four classes. The first three, in order of increasing difficulty, are Classes A, B, and C. These shall be referred to as AMA Pattern classes. The fourth class, Class D, shall be referred to as the FAI Pattern class, and is based on the World Championship event.

22.5.1 Except as noted in the FAI R/C rules section of this publication, paragraphs 22.16 and 22.17, all rules for the AMA Pattern classes shall apply to the FAI Pattern class.

22.5.2 In Classes C and D there shall be a sub-division into Novice and Expert. The methods of determining and controlling the Novice/Expert division are explained elsewhere.

22.6 CONTESTANT CLASSIFICATION:

22.6.1 Except as noted below, a contestant may enter any one pattern class at his own option. Once committed to a certain class, he will be allowed to move only to a higher skilled class in subsequent contests for the remainder of that particular year. However, if a flier completes a calendar year of competition without winning a single sanctioned event in the class he is committed to, he may if he so chooses, start the new calendar year in the next lower skill class. This does not apply to a flier who has reached his class by winning three contests in the next lower skill class.

22.6.2 Contestants shall advance through the classes as follows: After placing first, second, or third in three sanctioned contests, in which he must fly in his chosen class (except in the case where the contestant’s skill class is not being flown), he will be automatically advanced to the next higher class, i.e., from Class A to Class B, from Class B to Class C or D Novice, or from Class C or D Novice to Class C or D Expert.

NOTE: Contestants qualified for Class A Novice, or Expert are also qualified for Class D Novice or Expert.

22.6.3 The Contest Director of each AMA sanctioned R/C meet having Class A, B, C, D, E, D/N, or D/E events is responsible for upkeep of the classification system. He must require that only current AMA members be allowed to fly in the meet and that they all have valid FCC licenses. As soon as the first, second, and third place winners of each class are determined, the Contest Director shall fill out the appropriate spaces on the back of their membership cards, indicating the date, and the class won. He will also affix his verifying signature.

22.7 NUMBER OF FLIGHTS: There shall be no limit on the number of flights (other than that imposed by time available). Contest officials shall make every reasonable effort to ensure that all contestants receive equal opportunity to fly.

22.8 OFFICIAL FLIGHT: A flight is considered official if two maneuvers, other than takeoff and landing, have been judged. An attempted maneuver yielding zero points is still considered “judged.”
TIME LIMITS:
22.9.1 A Class A contestant is allotted a total of eight (8) minutes.
22.9.2 A Class B contestant is allotted a total of ten (10) minutes.
22.9.3 A Class C contestant (Novice or Expert) is allotted a total of ten (10) minutes.

CLASS B PATTERN:
The maneuvers are as follows:
1. Takeoff
2. Straight Flight Out
3. Procedure Turn
4. Straight Flight Back
5. Touch and Go
6. Three Axial Rolls
7. Three Inside Loops
8. Three Turn Spin
9. FAI Rolling Circle
10. FAI Horizontal Eight
11. Three Outside Loops
12. Slow Roll
13. Reverse Cuban Eight
14. Traffic Pattern Approach
15. Landing Perfection
16. Spot Landing

CLASS C PATTERN (NOVICE AND EXPERT):
The maneuvers are as follows:
1. Takeoff
2. Touch and Go
3. Three Horizontal Rolls
4. Three Inside Loops
5. Four Point Roll
6. Figure M
7. Horizontal Eight
8. Double Immelman
9. Three Outside Loops
10. Reverse Cuban Eight
11. Slow Roll
12. 180 Degree Turn
13. Top Hat
14. Three Turn Spin
15. Landing
16. Spot

DETERMINING THE WINNER:
22.11.1 The highest score for the total of the two best flights in Class A, B, or C shall be the winner. Maneuver points from repeat flights may not be added to earlier flights. Each flight is complete in itself. If the third best flight scores of the contestants concerned shall be used to determine the higher place, if only two flights have been scored during the normal contest time, the highest single flight score of the contestants concerned shall determine the higher place. There is no minimum number of flights which must be scored.
22.11.2 Determining the winner in Class D shall be done the same as for Classes A, B, and C except the total of the best THREE flights shall be used. Unless otherwise designated by the Contest Director, ties will be broken by a single flyoff which must take place within an hour of the normal contest finishing time.

FLIGHT PATTERN: The contestant must fly his entire flight according to the established Flight Pattern for his particular class and in the sequence listed. Maneuvers performed out of order will not be judged.
22.12.1 The contestant must call out each maneuver before he attempts to perform it. Call out should be given at least prior to execution. Also, the flyer should use the straight flight time at the end of each maneuver to announce, "maneuver complete."

CLASS A PATTERN:
The maneuvers are as follows:
1. Takeoff
2. Straight Flight Out
3. Procedure Turn
4. Straight Flight Back
5. Figure Eight
6. Three Rolls*
7. Immelman Turn
his plane and equipment to the pits. It shall be the responsibility of Event Director of his representative to notify contestants of start and end of 3 or 4 minute period.

c. Numbers 4, 5, and 6 on the Flight List shall have their planes and equipment in a ready box located near the flight line. As soon as a flight is completed, the No. 4 man becomes No. 3 and shall be requested to move his model and equipment onto the flight line. If he is not on hand to do so, he shall be dropped from the Flight List and the List advanced to fill his place. The Event Director or his representatives shall be responsible for notifying contestants when they are to move to ready box or flight line.

22.17.5 When technically possible and when judges and space are available, it is strongly recommended that two or more flights be flown simultaneously, under the following conditions:

a. Separate take-off and landing areas sufficiently spaced cross wind from each other to minimize engine noise and flight path interference.

b. Contestants flying simultaneously shall carefully check receiver and transmitter operation before take-off, to be sure no interference between them is possible.

c. Contestants flying simultaneously must be no more than three positions apart on the Flight List. Event Director or representative shall, where possible, select contestants at top of Flight List so that contestants flying on compatible frequencies are on flight line together.

d. Should a contestant oppose flying simultaneously with someone else, he may cancel his turn and re-sign at the bottom of the Flight List.

22.17.6 OFFICIALS. An Event Director, a Dispatcher-Recorder and Judges are the essential officials for an R/C Event. If possible, the Dispatcher-Recorder should have at least two helpers.

22.17.7 Each flight should be judged by at least two Judges, with their scores averaged to give final score for the flight. It is suggested that each maneuver be scored immediately after it is performed. Judges shall score maneuvers individually and without consultation between them. There should be enough judges available to establish a rotational procedure which will average out variations in judging.

22.18 DESCRIPTION OF MANEUVERS: A detailed description of each maneuver specified in the above patterns will be found in the AMA Radio Control Judges Guide, or the FAI Pattern rules.

AMA RADIO CONTROL JUDGES GUIDE

A. PURPOSE: The purpose of the AMA R/C Judges Guide is to furnish an accurate description of each maneuver listed in the three Pattern Event classes, and to provide a reference for use in establishing a uniformly high standard of judging in all AMA sanctioned contests.

Study of this guide by the competitor will help him learn exactly what is expected, while study by the judges will help them decide precisely how well the competitor comes up to these expectations.

B. PRINCIPLES: The principles of judging an R/C model should be based on the perfection with which the model simulates full scale aircraft performance. The main criteria for perfection in an individual maneuver can be classified as follows:

1. Precision of the maneuver
2. Positioning or display of the maneuver
3. Size or dimensions of the maneuver
4. Smoothness or gracefulness of the maneuver

All of these requirements must be met in order for a maneuver to be rated perfect. They are discussed below.

a. PRECISION: At the instant the competitor announces his next maneuver, the judge should form an image of the course the airplane should follow during the performance of the maneuver. The precision of the maneuver will then be based on how well the model tracks through the imaginary course.

Competitors will read this statement and exclaim "How am I to know what the judge imagines is a perfect course?" The answer to this is that once the model has locked in on the straight and level entry portion of a maneuver the only real disparity that can exist between the judge's and the competitor's image is the size of the maneuver. The judge will have some preconceived ideas about optimum size as discussed in a later section. However, the judge should modify his image if the first portion of the maneuver clearly demonstrates that the contestant intends to do a maneuver of much smaller or larger dimensions than the judge first imagined.

It will be noted that forming an image of the forthcoming maneuver is based on using the straight and level entry as a reference. If the contestant fails to go through this portion of the maneuver, it will be difficult and perhaps impossible to form an image before the start of the maneuver. The absence of a definite entry into a maneuver therefore increases the difficulty of judging its precision and competitors will recognize this as justification for downgrading.

The straight and level exit from a maneuver is one of the more valuable portions of the maneuver in evaluating how well the intended course of the maneuver was followed. The well-polished pilot will use it to announce "Maneuver completed," while the less competent pilot will often skip it in hopes that the judge will not notice that he deviated with respect to his entry heading. The absence of a well defined straight and level exit therefore should also result in downgrading.

b. POSITIONING: To achieve perfection, the competitor must position his maneuvers in a way that they can be easily judged. The first consideration on position is longitudinal distance from the competitor. It goes without saying that the judge should be located near the competitor so that they obtain identical views of the maneuver. The competitor should center his acrobatic maneuvers at an average distance of less than 300 feet from himself.

In short, the judge should be unmerciful if he gets the impression that the competitor is trying to hide his defects by flying at a great distance.

Positioning of maneuvers involves more than mere distance. They should also be presented in a relative direction which displays the most difficult aspects of the maneuver. Specifically, maneuvers which have circular symmetry (such as loops, Immelmans, Cuban

Eights, and FA1 Horizontal Eights) should have the "holes" in their circular path clearly visible, preferably in a plane exactly perpendicular to the line of sight to the model. The same applies to the Square Eight.

The diagrams used to describe these circular maneuvers in the AMA rule book define the best view to present to the judge. "End on" or "canted" presentation of these should result in downgrading since it increases the difficulty of judging the symmetry of figure 8's and the "tracking" of consecutive loops. While no special bonus is justified for exceptionally low altitude, excessively high altitude is cause for downgrading is severe. All maneuvers can be done at less than 300 feet longitudinal distance with altitudes that would not force the judge to look up at more than 45 degrees. If maneuvers are done at high altitudes and close to or above the transmitter in a way that they force the judge to look up vertically or near vertically, they should be downgraded. The main reason for this is that they cannot be properly oriented when performed directly overhead. However, a comment to competitors is in order here. This downgrading is almost an automatic reaction after a judge has been on the runway a few hours. He usually has a tired neck from looking at some maneuvers which must be followed overhead, and he is prone to be severe if he is forced to look there unnecessarily.

By the same token, most judges will refuse to even look at the remainder of a maneuver after an aircraft crosses the sun unnecessarily. There are also some places where the sun often cannot be avoided and the judge should follow through to the best of his ability. But he is completely justified in scoring zero if in his opinion the maneuver could have been placed elsewhere.

c. SIZE OF MANEUVERS: In the previous section it was pointed out that most maneuvers could be safely done at an average distance no greater than 300 feet from the competitor and judges, and at altitudes such that the line of sight to the model will seldom exceed a 45° elevation angle. These criteria place an upper limit of about 350 feet for the total vertical size of a maneuver. Most competitors and judges will recognize this as more than ample. It should also be recognized that 300 feet of horizontal distance is a maximum value and not a minimum. For example, an inside loop of 100 feet diameter at 150 feet longitudinal distance would stay within the 45° angle and a safe altitude and would be more clearly visible to the judge than at 300 feet distance. The competitor who performs loops in the 200 ft. region is therefore allowing the judge to evaluate them more critically and he should suffer no downgrading for positioning. On the other hand, a 100 ft. diameter loop at 300 ft. distance might be downgraded.

The optimum size of maneuvers is related to some extent on the size and normal flying speed of the model. For example, loops of 20 to 30 feet diameter done by a 2 ft. wing span airplane would not necessarily look poor or out of scale. However, 20 or 30 ft. diameter loops by a 50 mph multi job give the impression that the airplane was being set too low. The 300 feet altitude for this airplane would be uncomfortable if not "blacked out" due to the high "g" forces. Exceedingly small or tight maneuvers with unnecessarily high rates of roll, pitch or yaw do not simulate full scale performance and they should be downgraded accordingly.

d. SMOOTHNESS AND GRACEFULNESS: These two factors are inter-related with size of the maneuver and therefore again are related to normal flying speed of the model. Various judges and competitors will have different ideas of what actually constitutes smoothness and gracefulness. The most general definition must again be related to full scale simulation and the effects of the maneuver on an imaginary pilot or passenger in the plane on a touch-and-go or landing, for example, the judge might imagine the airplane as a DC-8 in which he is a passenger. Many of the so-called "smooths" encountered by RC models, in this equivalent situation, would result in shearing off of the landing gears and a total loss of the airline company's profits and equipment. It is recognized that few RC judges have ever been passengers in full scale aerobatic airplanes and therefore have no actual experience with the "g" forces in aerobatic maneuvers. Two to three g's would not be excessive in such performance, particular in violent maneuvers such as snap roll or spin. However, by comparison, a 30 ft. diameter loop at 50 mph results in about 10 g's, which is close to or excess of the design limits of most full scale aerobatic aircraft. Clearly, such tight maneuvers are not scale-like.

The matter of smoothness is basically related to scale like appearance. For example, a perfect set of consecutive rolls should have a constant roll rate from start to finish. A perfect loop must have a constant radius defining a perfect circle. It cannot be made up of a series of straight flight increments with sudden jerks placed between. Such sudden jerks represent high "g" forces well in excess of full scale tolerances and maneuvers should be downgraded for this.

C. ACCURATE AND CONSISTENT JUDGING: The most important aspect of consistent judging is for each judge to establish his standards and then maintain that standard throughout the meet. It is advisable for the context director or chief judge to hold a briefing prior to the start of the meet in order to make the standards as uniform as possible. This is done best by means of a practice flight which all judges score simultaneously and privately. After the flight, the defects in each maneuver should be discussed by all judges and a semblance of agreement reached about the severity of defects. Once this is done, however, and the contest is started, the individual judge should not alter his standards under any influence.

The context director should clearly define areas in which it is considered unsafe to fly, such as such as above spectators or over buildings, etc. It is highly recommended that the judges agree to register zero points for maneuvers done in these areas. Furthermore, for consistency, judges should exchange their scores immediately following an "over the crowd" maneuver. Nothing can cause more unrest among contestants than a zero and seven score of the same maneuver!

The responsibility for disqualifying pilots who persist in flying unsafely should be assigned to the judges by the C.D. The definition of unsafe areas should be absolutely unambiguous. For example, it should be stated that "maneuvers performed over the spectator area will be scored zero" and not that "maneuvers can be performed over the spectator area during "advance altitude". Obeying such safety regulations is just one more of the many pressures associated with winning a competition and the man who overcomes all pressures is more expert than one who does not.

D. JUDGING INDIVIDUAL MANEUVERS: The schedule of maneuvers to be performed is found in Section 22 of the AMA Rule Book. Each maneuver is to be judged individually on a basis of 0 to 10 points according to the degree of excellence. A common problem in judging is to score the first flights too high and then find there is no margin left to reward a superb flight. When in doubt give the lower score. Remember that perfection is not a relative thing. Perfection is that maneuver in which you see absolutely no flaws. It is not a common occurrence.

In the following section, a description of each maneuver is given and then a number of reasons for downgrading are listed. The maneuver should be downgraded according to (1) the number of defects observed; (2) the severity of the individual defects; and (3) the number of times any one defect occurs.

For example, a small single change in heading during the taxi portion of the touch and go would be considered one defect while two or three distinct turns would be considered two or three defects. It will be noted that for many maneuvers there are more than ten possible kinds of defects and that some of these can be repetitive. It will not be possible to downgrade one point for each defect or indeed we would have many negative scores.

A score of 10 should be given only if the maneuver is well positioned and no defects are observed. One or two minor defects should result in downgrading to at least an 8 while one severe defect should put it down to 6 as should a combination of three or four minor defects. Any merit in poor positioning should be decided at the start of the maneuver and also fed into the final score for the maneuver.
6. Model does not finish in level flight.
7. Model heading does not finish exactly opposite the direction of entry.

THREE INSIDE LOOPS: The model starts in straight and level flight, then pulls up into a smooth round loop, followed by a second and third loop in exactly the same path with a straight and level recovery to finish. The maneuver may be downgraded because:

A. During the first loop:
1. Loop not round and smooth.
2. Entry not level.
3. Loop deviates left or right.
4. Finish of loop not at same altitude as entry.
5. Model passes before start of second loop.

B. During the second loop:
1. Not on same heading as first loop.
2. Not the same circular path as first loop.
3. Loop deviates left or right.
4. Finish of loop not at same altitude as entry.
5. Model passes before start of third loop.

During the third loop:
1. Not on same heading as first loop.
2. Not on same circular path as first loop.
3. Loop deviates left or right.
4. Recovery not at same heading as entry.
5. Recovery not at same altitude as entry.
6. Recovery not level.

Note: Loops must appear rounded and superimposed to the ground-observer even in the presence of the wind.

Stall Turn

The model starts in straight and level flight and nose up to a vertical position. Yaws through 180°, then dives along a parallel path and finishes the maneuver with the plane level at the same altitude as the entry. The Stall Turn may be downgraded because:

1. Model not level at start.
2. Does not become exactly vertical.
3. Turns left or right during pull-up.
4. Does not yaw tightly through 180°.
5. Return path more than two wing-spans from entry path.
6. Return path not parallel to entry path.
7. Maneuver not finished at same altitude as entry.
8. Plane not level at finish of maneuver.
9. Model does not fly straight and level to complete maneuver.

Three Turn Spin

The plane establishes a heading by flying straight and level, pulls up into a stall and commences the spin through one, two, three turns and recovers to level flight on the same heading as the initial flight direction. The judge must watch carefully to be sure this is a spin and not a vertical roll or a spiral dive. In the spin, some part of the plane always intersects an imaginary vertical line along the path of descent. In the spiral dive, the plane circles around, but outside of, the imaginary vertical line. The spin may be downgraded because:

1. Initial heading is not level.
2. Commencement of first spin is sloppy or uncertain.
3. Does not do exactly three turns. Less than two or more than four turns should be scored zero.
4. Does not recover on same heading as initial heading.
5. If any of the three turns are spiral dives rather than spins, the score is zero.
6. Rate of rotation in spin is excessively rapid.
7. Does not finish level.
8. Does not fly straight and level for 50 feet.

FOUR POINT ROLL: From a straight and level upright flight path, the model is rolled 90 degrees and holds this attitude, with wings in a vertical position, long enough for it to be clearly defined. The model is then rolled another 90 degrees, in the same direction of rotation, and holds the inverted attitude long enough for it to be clearly defined. This is followed by another 90 degree roll in the same direction, bringing the ship to another knife edge position. Following a similar pause in the roll, the ship is finally rolled another 90 degrees to upright and level flight. The maneuver may be downgraded for the following reasons:

1. Model not level at start of roll.
2. The path traced by the model is not a straight line. (The plane does barrel roll segments or suffers changes in heading.)
3. Sudden corrections in heading between roll segments.
4. The axis of the fuselage veers out at too much of an angle to the flight path.
5. Plane changes altitude during roll.
6. Plane does not pause long enough between each segment of roll.
7. Wings are not exactly vertical at ¼ and ¾ positions.
8. Plane fails to do level flight at end of roll.

REVERSE CUBAN EIGHT: The model commences in straight and level flight, pulls up into a 45 degree climb, half rolls to inverted and proceeds to inside loop until it is again climbing at a 45 degree angle. The plane then does another half roll to inverted that should cross the flight path of the first half roll, then again proceeds to inside loop until it has reached straight and level flight on the same heading and altitude as the beginning. The maneuver shall be downgraded for the following:

1. Entry is not straight and level.
2. First roll not on 45 degree line.
3. Loop not round or deviates to left or right.
4. Second roll not on 45 degree line.
5. Middle of second roll does not cross middle point of first roll.

SLOW ROLL: The model commences from straight and level flight and then rolls slowly at a uniform rate through one complete rotation. The approximate time of the roll to be five seconds. Note: No downgrade for slight overtime. Downgrading shall result for any of the following reasons:

1. Model not level at entry.
2. Plane deviates from a straight line during roll.
3. Roll rate not uniform.
4. Plane does not roll through exactly one revolution.
5. Plane changes altitude during roll.
6. Plane changes heading.
7. Roll rate is too rapid resulting in much less than five seconds elapsed during roll.
8. Plane is not level at finish of roll.
9. Plane fails to do level flight at end of maneuver.

FAI TOP HAT: The model starts in straight level flight (pulls up into vertical climb and makes a half roll), then levels out inverted on the same heading as entry. After short inverted flight, model dives vertically, performs a half roll and finally recovers in straight level upright flight on same heading and height as entry. The Top Hat should be downgraded if:

1. Model does not start level.
2. Model does not go exactly vertical before starting roll.
3. Roll does not stop at exactly 180° from entry.
4. Model does not climb vertically for a brief period after completing roll.
5. Model does not go on an exactly horizontal inverted position after leveling out.
6. Model does not fly inverted for the same distance as the vertical climb and roll.
7. Model does not dive vertically briefly before starting half roll.
8. Second half roll not started at the same altitude as that where the first half roll was completed.
9. Second half roll not completed at same altitude as
that where first roll started.
10. Model does not dive vertically for a brief period after completing second half roll.
11. Model deviates left or right of the entry path at any point in the maneuver.
12. Model does not recover at same altitude and heading as entry.

**FAI ROLLING CIRCLE:** The model commences in straight level flight, makes half a roll, slows, and then makes a second half roll, subsequently making a half roll in the same direction of rotation as the first half roll, such that the model flies alternately upright and inverted in consecutive quadrants. The rolling circle shall be flown to the left. The direction of the half rolls is optional. The model recovers in straight level flight on the same heading and height as the entry. Downgrading shall result for any of the following reasons:

1. Plane not level at entry.
2. Half roll does not form an arc of a circle.
3. Model does not recover inverted at the 30° arc point.
4. Model heading is not at about 30° from entry at end of half roll.
5. Model does not fly a smooth circular inverted path from the instant it completes the half roll until reaching the 90° point.
6. Model does not roll upright at the same rate as previous half roll.
7. Model does not complete half roll in the same number of seconds as used for the previous half roll.
8. Model heading is not at about 30° from that at entry of the half roll.
9. Model does not fly a smooth circular upright path from the instant it completes the half roll until reaching the 180° point.
10. All items from 1 to 9 apply to second half of the maneuver in the same way as the first half.
11. The path of the complete maneuver must not deviate from a circle.
12. Model must depart from the maneuver at the same point in space on the same heading and altitude as the entry.

**FAI HORIZONTAL EIGHT:** The plane commences flying straight and level, pulls up into 1/4 of an inside loop, does one full inverted loop starting from straight down, then 1/4 of an inside loop finishing in straight and level flight. The Horizontal Eight may be downgraded because:

1. Entry not level.
2. First loop not round.
3. Plane deviates left or right during first loop.
4. Plane not vertical at start of second loop.
5. Second loop not the same diameter as first loop.
7. Second loop deviates left or right.
8. Does not finish level.
9. Does not finish on same heading as entry.
10. Does not finish at same altitude as entry.

**FAI DOUBLE IMELMAN:** Model commences in straight and level flight, pulls up into half an inside loop followed by a half roll to upright, flies straight and level for about one second, pushes down into half an outside loop followed by half a roll to upright, recovering in straight and level flight on the same heading and at the same altitude as the entry. Maneuver shall be downgraded for the following reasons:

1. Entry not straight and level.
2. Half loop not round.
3. Model deviates left or right during half roll.
4. Half loop not completed exactly above starting point.
5. Half roll does not start immediately after first half roll.
6. Roll is not on a straight line and on roll height from entry.
7. Model does not fly a smooth circular outside loop upon completion of half roll.
8. Plane holds straight flight too long before going to outside loop.
9. Half outside loop not round or same size as first half loop.
10. Model deviates left or right during half loop.
11. Half loop not completed exactly below starting point.
12. Final half roll does not start immediately after half outside loop.
13. Final half roll longer or shorter than first half roll.
14. Model does not finish on same heading and at same altitude as entry.
15. Plane fails to do straight and level flight at end of maneuver.

**THREE OUTSIDE LOOPS:** The model commences the outside loop flying straight and level, then does an inside loop and recovers flying straight and level on the same heading and altitude as the entry. The outside loops are downgraded in the same manner as the inside loops.

**180 DEGREE TURN:** The plane starts in straight and level flight, pulls up into a vertical climb, rolls 90 degrees, performs half of an outside loop, rolls 90 degrees in the opposite direction to the first quarter roll, and pulls out at the same altitude and height with a 180 degree heading change. The maneuver may be downgraded for the following reasons:

1. Entry is not level and height.
2. Pull up is not to exact vertical climb.
3. Roll is more or less than 90 degrees.
4. Path of roll is not straight vertical line.
5. Half outside loop deviates left or right.
6. Half loop is not smooth and round.
7. Second 90 degree roll path is not straight vertical line.
8. Pull out to level flight is sudden or jerky.
9. Pull out is not to same altitude and 180 degrees opposite heading to entry.
10. Plane fails to perform straight and level flight at end of maneuver.

*FIGURE M:* The model starts in straight and level flight, pulls up to a vertical attitude, performs a stall turn (left or right) through 180°, then makes 1/4 of an inverted loop pulling up again to vertical flight, performs a second stall turn in a direction opposite to the first stall turn and then recovers on the same altitude and heading as the entry. When viewed from the side, the model creates the letter "M". The maneuver should be downgraded for the following reasons:

1. Model not level at start.
2. Does not become vertical.
3. Turns left or right during pull up.
4. Turn radius at top of stall is longer than two wingspans.
5. Turns at top of stalls are less than 180°.
6. Diving paths are not parallel to climbing paths.
7. Bottom of inverted portion is at different altitude than entry.
8. Turning point of second stall turn is at different altitude from the first turn.
9. Maneuver not finished at same altitude as entry.
10. Plane not level at finish of maneuver.

**TRAFFIC PATTERN APPROACH:** The rectangular approach is commenced with the model flying into the wind above the transmitter, a turn of 90°, a second leg, a second turn of 90°, a downwind leg, a third turn of 90°, a crosswind leg, a fourth turn of 90° and straight flight toward the point of touchdown. The maneuver is finished just prior to the point of touchdown (500 feet altitude).

It is recommended that the descent start at the beginning of the downwind leg. However, wind or airplane conditions may dictate otherwise. Descent should therefore be judged only on smoothness and consistency not on which it actually starts.
Note: The contest director will announce whether the turns should be left or right. The rectangular approach may be downgraded because:
1. Legs of rectangle are not straight and perpendicular to each other.
2. The 90° turns are not smooth, precise, or sharp.
3. Galloping in pitch, yaw or roll during the approach.
4. Attempts to break out of pattern to go around again. Zero points!
5. Model climbs during approach.

Note: Since the Traffic Pattern Approach is not required in Class C, the Landing Perfection maneuver must be called out following completion of the Three Turn Spin. When the contestant has his plane lined up and on heading for the final approach, and not less than six (6) feet off the ground, he must announce the start of the Landing maneuver. From this point on, the Landing will be judged.

LANDING PERFECTION: At the conclusion of the final approach leg, the model continues to descend at a gradual rate and lands on the heading used in the final approach leg. After landing, the model must roll in a straight line and come to a complete stop. The landing should be downgraded if:
1. Approach during landing is too steep.
2. Galloping in pitch, yaw or roll during approach.
3. Model impacts or thuds onto ground due to lack of flare-out.
4. Model bounces on landing.
5. Model turns left or right while rolling to a stop.
   Turns necessary to avoid running off the runway may be excused if wind direction and spot location are adverse. However, this leniency applies only if the model lands in the spot and should not be employed in cases where the flyer accidentally lands near the edge of the runway outside the spot.
6. Landing is dead stick.
7. Model fails to make pronounced stop.
8. Model rolls too far away to accurately judge.
9. Model pitches over and makes ground contact with nose or wingtip.
10. If model flips over on its back or cartwheels on wings—0 points.

SPOT LANDING: Landing within the 100 foot circle results in automatic awarding of the same number of points obtained in landing perfection. All judges should show agreement on their score sheets (Not on the amount of score, just whether or not a spot landing was accomplished) and in the event of disagreement, a majority vote by the judges should dictate.

CONCLUSION OF FLIGHT: The official flight is finished at the moment the plane stops at the end of its landing roll. At this point the contestant announces “flight complete” and immediately taxis his plane off the runway to whatever area the Contest Director designates. If landing was deadstick, pilot or helper shall retrieve plane as soon as permitted by official in charge of flight line.
